Part I

Overview

Chapter 1

Descriptions of Problems

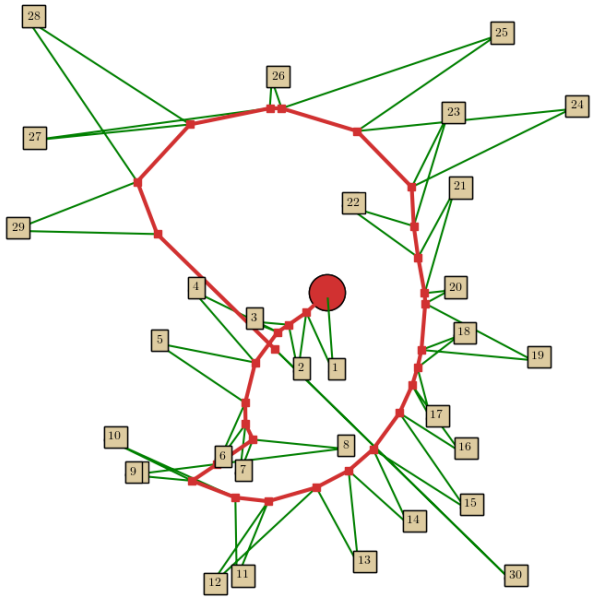

Figure 1.1: An Example of a classic Horsefly tour with $\varphi = 5$. The red dot indicates the initial position of the horse and fly, given as part of the input. The ordering of sites shown has been computed with a greedy algorithm which will be described later

The Horsefly problem is a generalization of the well-known Euclidean Traveling Salesman Problem. In the most basic version of the Horsefly problem (which we call **"Classic Horsefly"**), we are given a set of sites, the initial position of a truck(horse) with a drone(fly) mounted on top, and the speed of the drone-speed φ. [1] [2].

The goal is to compute a tour for both the truck and the drone to deliver package to sites as quickly as possible. For delivery, a drone must pick up a package from the truck, fly to the site and come back to the truck to pick up the next package for delivery to another site. [3] Both the truck and drone must coordinate their motions to minimize the time it takes for all the sites to get their

[1] The speed of the truck is always assumed to be 1 in any of the problem variations we will be considering in this report.

[2] φ is also called the "speed ratio".

[3] The drone is assumed to be able to carry at most one package at a time

packages. Figure 1.1 gives an example of such a tour computed using a greedy heuristic for $\varphi = 5$.

This suite of programs implement several experimental heuristics, to solve the above NP-hard problem and some of its variations approximately. In this short chapter, we give a description of the problem variations that we will be tackling. Each of the problems, has a corresponding chapter in Part 2, where these heuristics are described and implemented. We also give comparative analyses of their experimental performance on various problem instances.

Classic Horsefly This problem has already described in the introduction.

Segment Horsefly In this variation, the path of the truck is restricted to that of a segment, which we can consider without loss of generality to be $[0, 1]$. All sites, without loss of generality lie in the upper-half plane $\mathbb{R}^2_+$.

Fixed Route Horsefly This is the obvious generalization of Segment Horsefly, where the path which the truck is restricted to travel is a piece-wise linear polygonal path. [4] Both the initial position of the truck and the drone are given. The sites to be serviced are allowed to lie anywhere in $\mathbb{R}^2$. Two further variations are possible in this setting, one in which the truck is allowed reversals and the other in which it is not.

One Horse, Two Flies The truck is now equipped with two drones. Otherwise the setting, is exactly the same as in classic horsefly. Each drone can carry only one package at a time. The drones must fly back and forth between the truck and the sites to deliver the packages. We allow the possibility that both the drones can land at the same time and place on the truck to pick up their next package. [5]

Reverse Horsefly In this model, each site (not the truck!) is equipped with a drone, which fly *towards* the truck to pick up their packages. We need to coordinate the motion of the truck and drone so that the time it takes for the last drone to pick up its package (the "makespan") is minimized.

Bounded Distance Horsefly In most real-world scenarios, the drone will not be able to (or allowed to) go more than a certain distance R from the truck. Thus with the same settings as the classic horsefly, but with the added constraint of the drone and the truck never being more than a distance R from the truck, how would one compute the truck and drone paths to minimize the makespan of the deliveries?

Watchman Horsefly In place of the TSP, we generalize the Watchman route problem here. [6] We are given as input a simple polygon and the initial position of a truck and a drone. The drone has a camera mounted on top which is assumed to have 360° vision. Both the truck and drone can move, but the drone can move at most euclidean distance [7] R from the truck.

[4] More generally, the truck will be restricted to travelling on a road network, which would typically be modelled as a graph embedded in the plane.

[5] In reality, one of the drones will have to wait for a small amount of time while the other is retrieving its package. In a more realisting model, we would need to take into account this "waiting time" too.

[6] although abstractly, the Watchman route problem can be viewed as a kind of TSP

[7] The version where instead geodesic distance is considered is also interesting

We want every point in the polygon to be seen by the drone at least once. The goal is to minimize the time it takes for the drone to be able to see every point in the simple polygon. In other words, we want to minimize the time it takes for the drone (moving in coordinattion with the truck) to patrol the entire polygon.

Chapter 2

Installation and Use

To run these programs you will need to install Docker, an open-source containerization program that is easily installable on Windows 10[1], MacOS, and almost any GNU/Linux distribution. For a quick introduction to containerization, watch the first two minutes of https://youtu.be/_dfLOzuIg2o

The nice thing about Docker is that it makes it easy to run softwares on different OS'es portably and neatly side-steps the dependency hell problem (https://en.wikipedia.org/wiki/Dependency_hell.) The headache of installing different library dependencies correctly on different machines running different OS'es, is replaced **only** by learning how to install Docker and to set up an X-windows connection between the host OS and an instantiated container running GNU/Linux.

A. [*Get Docker*] For installation instrutions watch

GNU/Linux https://youtu.be/KCckWweNSrM

Windows https://youtu.be/ymlWt1MqURY

MacOS https://youtu.be/MU8HUVlJTEY

B. [*Download customized Ubuntu image*] `docker pull gtelang/ubuntu_customized` [2]

C. [*Clone repository*] `git clone gtelang/horseflies_literate.git`

D. [*Mount and Launch*]

For GNU/Linux Open up your favorite terminal emulator, such xterm and then

- Copy to clipboard the output of `xauth list`
- `cd horseflies_literate`
- `docker run -it --name horsefly_container --net=host -e DISPLAY -v /tmp/.X11-unix -v `pwd`
- `cd horseflies_mnt`
- `xauth add` *<paste-from-clipboard>*

[1] You might need to turn on virtualization explicitly in your BIOS, after installing Docker as I needed to while setting Docker up on Windows. Here is a snapshot of an image when turning on Intel's virtualization technology through the BIOS: https://images.techhive.com/images/article/2015/09/virtualbox_vt-x_amd-v_error04_phoenix-100612961-large.idge.jpg

[2] The customized Ubuntu image is approximately 7 GB which contains all the libraries (e.g. CGAL, VTK, numpy, and matplotlib) that I typically use to run my research codes portably.On my home internet connection downloading this Ubuntu-image typically takes about 5 minutes.

For Windows I had to follow the instructions in https://dev.to/darksmile92/run-gui-app-in-linux-Docker-container-on-windows-host-4kde to be able to run graphical user applications

E. [*Run experiments*] If you want to run all the experiments as described in the paper again to reproduce the reported results on your machine, then run [3],
`python main.py --run-all-experiments`.

If you want to run a specific experiment, then run
`python main.py --run-experiment <experiment-name>`.

See Index for a list of all the experiments.

F. [*Test algorithms interactively*] If you want to test the algorithms in interactive mode (where you get to select the problem-type, mouse-in the sites on a canvas, set the initial position of the truck and drone and set φ), run `python main.py --<problem-name>`. The list of problems are the same as that given in the previous chapter. The problem name consists of all lower-case letters with spaces replaced by hyphens.

Thus for instance "Watchman Horsefly" becomes `watchman-horsefly` and "One Horse Two Flies" becomes `one-horse-two-flies`.

To interactively experiment with different algorithms for, say, the Watchman Horsefly problem , type at the terminal `python main.py --watchman-horsefly`

If you want to delete the Ubuntu image and any associated containers run the command [4]

```
docker rm -f horsefly_container; docker rmi -f ubuntu_customized
```

That's it! Happy horseflying!

[3] Allowing, of course, for differences between your machine's CPU and mine when it comes to reporting absolute running time

[4] the ubuntu image is 7GB afterall!

Part II

Programs

Chapter 3

Overview of the Code Base

NOTE: The style of presentation in this chapter has been adapted from Chapter 2 of the Nuweb reference manual http://nuweb.sourceforge.net/nuweb.pdf

Almost all of the code has been written in Python 2.7 and tested using the standard CPython implementation of the language. In some cases, calls will be made to external C++ libraries (mostly CGAL and VTK) using SWIG (http://www.swig.org/). This is either for speeding up a slow routine or to use a function that is not available in any existing Python package.

6 directories, 24 files
```

There are three principal directories

`webs/` This contains the source code for the entire project written in the nuweb format along with documents (mostly images) needed during the compilation of the LaTeX files which will be extracted from the `.web` files.

`src/` This contains the source code for the entire project "tangled" (i.e. extracted) from the `.web` files.

`tex/` This contains the monolithic `horseflies.tex` extracted from the `.web` files and a bunch of other supporing LaTeX files. It also contains the final compiled `horseflies.pdf` (the current document) which contains the documentation of the project, interwoven with code-chunks and cross-references between them along with the experimental results.

The files in `src` and `tex` should not be touched. Any editing required should be done to the `.web` files, which should then be weaved and tangled using the script `weave-tangle.sh` in the `webs` directory.

The Main Files

3.2.1 Each of the files with prefix `problem-*` contain implmentations of algorithms for one specific problem. Thus `problem-watchman-horsefly.py` contains algorithms for approximately solving the Watchman Horsefly problem.

All such files are in the directory `src/lib/`

3.2.2 Similarly, each of the files with prefix `expt-*` contain code for testing hypotheses regarding a problem, generating counter-examples or comparing the experimental performance of the algorithm implementations for each of the problems. Thus `expt-watchman-horsefly.py` contains code for performing experiments related to the Watchman Horsefly problem.

All such files are in the directory `src/expt/`

3.2.3 The file `main.py` in the top-level folder is the *entry-point* for running code. Its only job is to parse the command-line arguments and pass relevant information to the handler functions for each problem and experiment.

Each problem or experiment has a handler routine that effectively acts as a kind of "main" function for that module that does some house-keeping duties by parsing the command-line arguments passed by main, setting up the canvas by calling the appropriate graphics routines and calling the algorithms on the input specified through the canvas.

"../main.py" 13≡

```
import sys
sys.path.append('src/lib')

import problem_classic_horsefly as chf
#import problem_segment_horsefly as shf
#import problem_one_horse_two_flies as oh2f

if __name__=="__main__":
     # Select algorithm or experiment
     if (len(sys.argv)==1):
          print "Specify the problem or experiment you want to run"
          sys.exit()

     elif sys.argv[1] == "--problem-classic-horsefly":
          chf.run_handler()

     elif sys.argv[1] == "--problem-segment-horsefly":
          shf.run_handler()

     elif sys.argv[1] == "--problem-one-horse-two-flies":
          oh2f.run_handler()

     else:
          print "Option not recognized"
          sys.exit()
```

◇

Support Files

3.3.1 These files contain common utility functions that will be useful for manipulating data-structures, common plotting and graphics routines for all horsefly-type problems. All such files have the prefix `utils-*`

All such files are in the directory `src/lib/`

3.3.2 To automate testing of code during implementations, tests for various routines across the entire code-base have been written in files with prefix `test-*`.

Each of the main files have a corresponding test file. Tests for functions in the support files and experimental files have all been implemented in the files `test-utilities.py` and `test-experiments.py` respectively.

All such files are in the directory `src/test/`

Chapter 4

Some (Boring) Utility Functions

We will be needing some utility functions, for drawing and manipulating data-structures which will be implemented in files separate from `problem_classic_horsefly.py`. All such files will be prefixed with the work `utils_`. Many of the important common utility functions are defined here; others will be defined on the fly throughout the rest of the report. This chapter just collects the most important of the functions for the sake of clarity of exposition in the later chapters.

Graphical Utilities

Here We will develop routines to interactively insert points onto a Matplotlib canvas and clear the canvas. Almost all variants of the horsefly problem will involve mousing in sites and the initial position of the horse and fly. These points will typically be represented by small circular patches. The type of the point will be indicated by its color and size e.g. intial position of truck and drone will typically be represented by a large red dot while and the sites by smaller blue dots.

Matplotlib has extensive support for inserting such circular patches onto its canvas with mouse-clicks. Each such graphical canvas corresponds (roughly) to Matplotlib figure object instance. Each figure consists of several Axes objects which contains most of the figure elements i.e. the Axes objects correspond to the "drawing area" of the canvas.

4.1.1 First we set up the axes limits, dimensions and other configuration quantities which will correspond to the "without loss of generality" assumptions made in the statements of the horsefly problems. We also need to set up the axes limits, dimensions, and other fluff. The following fragment defines a function which "normalizes" a drawing area by setting up the x and y limits and making the aspect ratio of the axes object the same i.e. 1.0. Since Matplotlib is principally a plotting software, this is not the default behavior, since scales on the x and y axes are adjusted according to the data to be plotted.

`"../src/lib/utils_graphics.py"` 15≡

```
from matplotlib import rc
from colorama import Fore
```

```
from colorama import Style
from scipy.optimize import minimize
from sklearn.cluster import KMeans
import argparse
import itertools
import math
import matplotlib as mpl
import matplotlib.pyplot as plt
import numpy as np
import os
import pprint as pp
import randomcolor
import sys
import time

xlim, ylim = [0,1], [0,1]

def applyAxCorrection(ax):
      ax.set_xlim([xlim[0], xlim[1]])
      ax.set_ylim([ylim[0], ylim[1]])
      ax.set_aspect(1.0)
◇
```

File defined by 15, 16, 17ab.

4.1.2 Next, given an axes object (i.e. a drawing area on a figure object) we need a function to delete and remove all the graphical objects drawn on it.

"../src/lib/utils_graphics.py" 16≡

```
def clearPatches(ax):
    # Get indices cooresponding to the polygon patches
    for index , patch in zip(range(len(ax.patches)), ax.patches):
        if isinstance(patch, mpl.patches.Polygon) == True:
            patch.remove()

    # Remove line patches. These get inserted during the r=2 case,
    # For some strange reason matplotlib does not consider line objects
    # as patches.
    ax.lines[:]=[]

    #pp.pprint (ax.patches) # To verify that none of the patches are
    # polyon patches corresponding to clusters.
    applyAxCorrection(ax)
◇
```

File defined by 15, 16, 17ab.

4.1.3 Now remove the patches which were rendered for each cluster Unfortunately, this step has to be done manually, the canvas patch of a cluster and the corresponding object in memory are not reactively connected.I presume, this behavioue can be achieved by sub-classing.

"../src/lib/utils_graphics.py" 17a≡

```
def clearAxPolygonPatches(ax):

    # Get indices cooresponding to the polygon patches
    for index , patch in zip(range(len(ax.patches)), ax.patches):
        if isinstance(patch, mpl.patches.Polygon) == True:
            patch.remove()

    # Remove line patches. These get inserted during the r=2 case,
    # For some strange reason matplotlib does not consider line objects
    # as patches.
    ax.lines[:]=[]

    # To verify that none of the patches
    # are polyon patches corresponding
    # to clusters.
    #pp.pprint (ax.patches)
    applyAxCorrection(ax)
◇
```

File defined by 15, 16, 17ab.

4.1.4 Now for one of the most important routines for drawing on the canvas! To insert the sites, we double-click the left mouse button and to insert the initial position of the horse and fly we double-click the right mouse-button.

Note that the left mouse-button corresponds to button 1 and right mouse button to button 3 in the code-fragment below.

"../src/lib/utils_graphics.py" 17b≡

```
## Also modify to enter initial position of horse and fly
def wrapperEnterRunPoints(fig, ax, run):
    """ Create a closure for the mouseClick event.
```

```
"""
def _enterPoints(event):
    if event.name     == 'button_press_event'      and \
       (event.button   == 1 or event.button == 3)  and \
       event.dblclick == True                      and \
       event.xdata    != None                      and \
       event.ydata    != None:

         if event.button == 1:
           newPoint = (event.xdata, event.ydata)
           run.sites.append( newPoint  )
           patchSize  = (xlim[1]-xlim[0])/140.0

           ax.add_patch( mpl.patches.Circle( newPoint,
                                        radius = patchSize,
                                        facecolor='blue',
                                        edgecolor='black'   )  )
           ax.set_title('Points Inserted: ' + str(len(run.sites)), \
                        fontdict={'fontsize':40})

         if event.button == 3:
             inithorseposn = (event.xdata, event.ydata)
             run.inithorseposn = inithorseposn
             patchSize  = (xlim[1]-xlim[0])/70.0

             # TODO: remove the previous red patches,
             # which containg ht eold position
             # of the horse and fly. Doing this is
             # slightly painful, hence keeping it
             # for later
             ax.add_patch( mpl.patches.Circle( inithorseposn,
                                          radius = patchSize,
                                          facecolor= '#D13131', #'red',
                                          edgecolor='black'   )  )

         # It is inefficient to clear the polygon patches inside the
         # enterpoints loop as done here.
         # I have just done this for simplicity: the intended behaviour
         # at any rate, is
         # to clear all the polygon patches from the axes object,
         # once the user starts entering in MORE POINTS TO THE CLOUD
         # for which the clustering was just computed and rendered.
         # The moment the user starts entering new points,
         # the previous polygon patches are garbage collected.
         clearAxPolygonPatches(ax)
         applyAxCorrection(ax)
         fig.canvas.draw()
```

```
        return _enterPoints
    ◇
```

File defined by 15, 16, 17ab.

Algorithmic Utilities

4.2.1 Given a list of points $[p_0, p_1, p_2, ...p_{n-1}]$. the following function returns, $[p_1 - p_0, p_2 - p_1, ..., p_{n-1} - p_{n-2}]$ i.e. it converts the list of points into a consecutive list of numpy vectors. Points should be lists or tuples of length 2

"../src/lib/utils_algo.py" 19≡

```
    import numpy as np
    import random
    from colorama import Fore
    from colorama import Style

    def vector_chain_from_point_list(pts):
        """ Given a list of points [p0,p1,p2,....p(n-1)]
        Make it into a list of numpy vectors
        [p1-p0, p2-p1,...,p(n-1)-p(n-2)]

        Points should be lists or tuples of length 2
        """
        vec_chain = []
        for pair in zip(pts, pts[1:]):
            tail= np.array (pair[0])
            head= np.array (pair[1])
            vec_chain.append(head-tail)

        return vec_chain
    ◇
```

File defined by 19, 20ab, 21ab.

4.2.2 Given a polygonal chain, an important computation is to calculate its length. Typically used for computing the length of the horse's and fly's tours.

"../src/lib/utils_algo.py" 20a≡

```
def length_polygonal_chain(pts):
    """ Given a list of points [p0,p1,p2,....p(n-1)]
    calculate the length of its segments.

    Points should be lists or tuples of length 2

    If no points or just one point is given in the list of
    points, then 0 is returned.
    """
    vec_chain = vector_chain_from_point_list(pts)

    acc = 0
    for vec in vec_chain:
        acc = acc + np.linalg.norm(vec)
    return acc
◇
```

File defined by 19, 20ab, 21ab.

4.2.3 The following routine is useful on long lists returned from external solvers. Often point-data is given to and returned from these external routines in flattened form. The following routines are needed to convert such a "flattened" list into a list of points and vice versa.

"../src/lib/utils_algo.py" 20b≡

```
def pointify_vector (x):
    """ Convert a vector of even length
    into a vector of points. i.e.
    [x0,x1,x2,...x2n] -> [[x0,x1],[x2,x3],,..[x2n-1,x2n]]
    """
    if len(x) % 2 == 0:
        pts = []
        for i in range(len(x))[::2]:
            pts.append( [x[i],x[i+1]] )
        return pts
    else :
        sys.exit('List of items does not have an even length to be able to be pointifyed')

def flatten_list_of_lists(l):
    """ Flatten vector
      e.g.  [[0,1],[2,3],[4,5]] -> [0,1,2,3,4,5]
    """
    return [item for sublist in l for item in sublist]
```

◇

File defined by 19, 20ab, 21ab.

4.2.4 Python's default print function prints each list on a single line. For debugging purposes, it helps to print a list with one item per line.

"../src/lib/utils_algo.py" 21a≡

```
def print_list(xs):
    """ Print each item of a list on new line
    """
    for x in xs:
        print x
```

◇

File defined by 19, 20ab, 21ab.

4.2.5 The following routines are self-explanatory and are hence gathered into one chunk.

"../src/lib/utils_algo.py" 21b≡

```
def partial_sums( xs ):
    """
    List of partial sums
    [4,2,3] -> [4,6,9]
    """
    psum = 0
    acc = []
    for x in xs:
        psum = psum+x
        acc.append( psum )

    return acc

def are_site_orderings_equal(sites1, sites2):
    """
    For two given lists of points test if they are
    equal or not. We do this by checking the Linfinity
    norm.
    """
```

```
    for (x1,y1), (x2,y2) in zip(sites1, sites2):
        if (x1-x2)**2 + (y1-y2)**2 > 1e-8:

            print Fore.BLUE+ "Site Orderings are not equal"
            print sites1
            print sites2
            print '------------------------' + Style.RESET_ALL
            return False

    return True

    print "\n\n\n\n----------------------"

def bunch_of_random_points(numpts):
    cluster_size = int(np.sqrt(numpts))
    numcenters   = cluster_size

    import scipy
    import random
    centers = scipy.rand(numcenters,2).tolist()

    scale = 4.0
    points = []
    for c in centers:
        cx = c[0]
        cy = c[1]

        sq_size      = min(cx,1-cx,cy, 1-cy)
        cluster_size = int(np.sqrt(numpts))
        loc_pts_x    = np.random.uniform(low=cx-sq_size/scale,

Chapter 5

Classic Horsefly

Module Overview

5.1.1 All algorithms to solve the classic horsefly problems have been implemented in the file `problem_classic_horsefly.py`. Here is a high-level view of the module. The `run_handler` function acts as a kind of main function for this module. This function is called from `main.py` which then processes the command-line arguments and runs the experimental or interactive sections of the code.

`"../src/lib/problem_classic_horsefly.py"` 24a≡

```

5.2.2 The key-press handler function detects the keys pressed by the user when the canvas is in active focus. This function allows you to set some of the input parameters like speed ratio φ, or selecting an algorithm interactively at the command-line, generating a bunch of uniform or non-uniformly distributed points on the canvas, or just plain clearing the canvas for inserting a fresh input set of points.

⟨ *Define key-press handler* 25 ⟩ ≡

```
# The key-stack argument is mutable! I am using this hack to my advantage.

◇
```

Fragment referenced in 25.

5.2.4 This chunk generates points uniformly or non-uniformly distributed in the unit square $[0,1]^2$ in the Matplotlib canvas. I will document the schemes used for generating the non-uniformly distributed points later. These schemes are important to test the effectiveness of the horsefly algorithms. Uniform point clouds do no highlight the weaknesses of sequencing algorithms as David Johnson implies in his article on how to write experimental algorithm papers when he talks about algorithms for the TSP.

⟨ *Generate a bunch of uniform or non-uniform random points on the canvas* 27 ⟩ ≡

```
numpts = int(sys.argv[1])
run.clearAllStates()
ax.cla()

utils_graphics.applyAxCorrection(ax)
ax.set_xticks([])
ax.set_yticks([])

fig.texts = []

import scipy
if event.key in ['n', 'N']: # Non-uniform random points
        run.sites = utils_algo.bunch_of_random_points(numpts)
else : # Uniform random points
```

```
            run.sites = scipy.rand(numpts,2).tolist()

    patchSize  = (utils_graphics.xlim[1]-utils_graphics.xlim[0])/140.0

    for site in run.sites:
        ax.add_patch(mpl.patches.Circle(site, radius = patchSize, \
                     facecolor='blue',edgecolor='black' ))

    ax.set_title('Points : ' + str(len(run.sites)), fontdict={'fontsize':40})
    fig.canvas.draw()
    ◇

            return sites + inithorseposn
```

◇

Fragment referenced in 24a.

Now that all the boring boiler-plate and handler codes have been written, its finally time for algorithmic ideas and implementations! Every algorithm is given an algorithmic overview followed by the detailed steps woven together with the source code.

Any local utility functions, needed for algorithmic or graphing purposes are collected at the end of this chapter.

Algorithm: Greedy—Nearest Neighbor

5.4.1 Algorithmic Overview

5.4.2 Algorithmic Details

⟨ *Algorithms for classic horsefly* 31 ⟩ ≡

```
def algo_greedy(sites, inithorseposn, phi, post_optimizer):
      """
      This implements the greedy algorithm for the canonical greedy
      algorithm for collinear horsefly, and then uses the ordering
      obtained to get the exact tour for that given ordering.

      Many variations on this are possible. However, this algorithm
      is simple and may be more amenable to theoretical analysis.

      We will need an inequality for collapsing chains however.
      """
      def next_rendezvous_point_for_horse_and_fly(horseposn, site):
            """
            Just use the exact solution when there is a single site.
            No need to use the collinear horse formula which you can
            explicitly derive. That formula is  an important super-special
            case however to benchmark quality of solution.
            """

Local Utility Functions

5.5.1 For a given initial position of horse and fly return a function computing the tour length. The returned function computes the tour length in the order of the list of stops provided beginning with the initial position of horse and fly. Since the horse speed = 1, the tour length = time taken by horse to traverse the route.

This is in other words the objective function.

⟨ *Local utility functions for classic horsefly* 35a ⟩ ≡

```
def tour_length(horseflyinit):
   def _tourlength (x):

        # the first point on the tour is the
        # initial position of horse and fly
        # Append this to the solution x = [x0,x1,x2,....]
        # at the front
        htour = np.append(horseflyinit, x)
        length = 0

        for i in range(len(htour))[:-3:2]:
                length = length + \
                        np.linalg.norm([htour[i+2] - htour[i], \
                                        htour[i+3] - htour[i+1]])
        return length

   return _tourlength
```

5.5.2 It is possible that some heuristics might return non-negligible waiting times. Hence I am writing a separate function which adds the waiting time (if it is positive) to the length of each link of the tour. Again note that because speed of horse = 1, we can add "time" to "distance".

⟨ *Local utility functions for classic horsefly* 35b ⟩ ≡

```
def tour_length_with_waiting_time_included(tour_points, horse_waiting_times, horseflyinit):
      tour_points   = np.asarray([horseflyinit] + tour_points)
      tour_links    = zip(tour_points, tour_points[1:])
```

```
        # the +1 because the inital position has been tacked on at the beginning
        # the solvers written the tour points except for the starting position
        # because that is known and part of the input. For this function
        # I need to tack it on for tour length
        assert(len(tour_points) == len(horse_waiting_times)+1)

        sum = 0
        for i in range(len(horse_waiting_times)):

            # Negative waiting times means drone/fly was waiting
            # at rendezvous point
            if horse_waiting_times[i] >= 0:
                wait = horse_waiting_times[i]
            else:
                wait = 0

            sum += wait + np.linalg.norm(tour_links[i][0] - tour_links[i][1], ord=2) #
        return sum
```
